

κ -misspecification: safety vs true capability with controller assuming $\kappa_{asm} = 0.98$ ($N = 10$, $n_{adv} = 5$, nearest-adversary, $n = 30$, bootstrap 95% CIs)
 AR degrades gracefully when $\kappa_{true} > \kappa_{asm}$ (no cliff) and is conservative-but-safe when $\kappa_{true} < \kappa_{asm}$ — fails safe

(a) Barrier violation rate vs true capability

(b) Collision rate vs true capability
